Growing context-sensitive grammar A growing context-sensitive language is a context-sensitive language generated by these grammars. In formal language theory, a growing context-sensitive grammar is a context-sensitive grammar in which the productions increase the length of the sentences. In formal language theory, a growing context-sensitive grammar is a context-sensitive grammar in which the productions increase the length of the sentences being generated. These grammars are thus noncontracting and context-sensitive.

These grammars were introduced by Dahlhaus and Warmuth. They were later shown to be equivalent to the acyclic context-sensitive grammars. Membership in any growing context-sensitive language is polynomial time computable; however, the uniform problem... α a single nonterminal symbol, and $\alpha \alpha$ $\{\displaystyle A\}$

Context-sensitive language Unlike context-free grammars, which can apply rules regardless of context, context-sensitive grammars allow rules to be applied only when specific neighboring symbols are present, enabling them to express dependencies and agreements between distant parts of a string. In formal language theory, a context-sensitive language is a formal language that can be defined by a context-sensitive grammar, where the applicability of a production rule may depend on the surrounding context of symbols.

Context-free language In formal language theory, a context-free language (CFL), also called a Chomsky type-2 language, is a language generated by a context-free grammar (CFG). In formal language theory, a context-free language (CFL), also called a Chomsky type-2 language, is a language generated by a context-free grammar (CFG).

DCFGs are of great practical interest, as they can be parsed in linear time and in fact a parser can be automatically generated from the grammar by a parser generator. They are thus widely used throughout computer science. Various restricted forms of DCFGs can be parsed by simpler, less resource-intensive parsers, and thus are often used. These grammar classes are referred to...

Grammar induction Other classes Grammar induction (or grammatical inference) is the process in machine learning of learning a formal

grammar (usually as a collection of re-write rules or productions or alternatively as a finite-state machine or automaton of some kind) from a set of observations, thus constructing a model which accounts for the characteristics of the observed objects. More generally, grammatical inference is that branch of machine learning where the instance space consists of discrete combinatorial objects such as strings, trees and graphs. inference of context-free grammars and richer formalisms, such as multiple context-free grammars and parallel multiple context-free grammars

These languages correspond to type-1 languages in the Chomsky hierarchy and are equivalently defined by noncontracting grammars (grammars where production rules never decrease the total length of a string). Context-sensitive languages can model natural language phenomena such as subject-verb agreement, cross... $\{\alpha\}$ In these grammars the "start symbol" S does not appear on the right hand side of any production rule and the length of the right hand side of each production exceeds the length of the left side, unless the left side is S .

Deterministic context-free grammar In formal grammar theory, the deterministic context-free grammars (DCFGs) are a proper subset of the context-free grammars. They are the subset of context-free grammars that can be derived from deterministic pushdown automata, and they generate the deterministic context-free languages. They are the subset of context-free In formal grammar theory, the deterministic context-free grammars (DCFGs) are a proper subset of the context-free grammars. DCFGs are always unambiguous, and are an important subclass of unambiguous CFGs; there are non-deterministic unambiguous CFGs, however

Probabilistic context-free grammar A probabilistic grammar's validity is constrained by context of its training dataset. Each production is assigned a probability. These probabilities can be viewed as parameters of the model, and for large problems it is convenient to learn these parameters via machine learning. In theoretical linguistics and computational linguistics, probabilistic context free grammars (PCFGs) extend context-free grammars, similar to how hidden In theoretical linguistics and computational linguistics, probabilistic context free grammars (PCFGs) extend context-free grammars, similar to how hidden Markov models extend regular grammars. The probability of a derivation (parse) is the product of the probabilities of the productions used in that derivation

Ambiguous grammar g . Every non-empty context-free language admits an ambiguous grammar by introducing ϵ . In computer science, an ambiguous grammar is a context-free grammar for which there exists a string that can have more than one leftmost derivation or In computer science, an ambiguous grammar is a context-free grammar for which there exists a string that can have more than one leftmost derivation or parse tree. A language that only admits ambiguous grammars is called an inherently ambiguous language. Deterministic context-free grammars are always unambiguous, and are an important subclass of unambiguous grammars; there are non-deterministic unambiguous grammars, however. a duplicate rule

In particular, in a context-free grammar, each production rule is of the form $A \rightarrow \alpha$ (α can be applied to a nonterminal symbol regardless of its context. α can be empty). Regardless of which symbols surround it, the single nonterminal A can be replaced by α .

Context-sensitive grammar Context-sensitive grammars are more general than context-free grammars, in the sense that there are languages that can be described by a CSG but not by a context-free grammar. A context-sensitive grammar (CSG) is a formal grammar in which the left-hand sides and right-hand sides of any production rules may be surrounded by a context of terminal and nonterminal symbols. Context-sensitive grammars are less general (in the same sense) than unrestricted grammars. Thus, CSGs are positioned between context-free and unrestricted grammars in the Chomsky hierarchy.

PCFGs originated from grammar theory, and have application in areas as diverse as natural language processing to the study the structure of RNA molecules and design of programming languages. Designing efficient...

Context-free grammar In formal language theory, a context-free grammar (CFG) is a formal grammar whose production rules can be applied to a nonterminal symbol regardless of its context. In formal language theory, a context-free grammar (CFG) is a formal grammar whose production rules are of the form $A \rightarrow \alpha$.

A formal language that can be described by a context-sensitive grammar, or, equivalently, by a noncontracting grammar or a linear bounded automaton, is called a context-sensitive language. Some textbooks actually define CSGs as non-contracting. A context-sensitive language is a language L such that $L \in \text{CSG}$. For computer programming languages, the reference grammar is often ambiguous, due to issues such as the dangling else problem. If present, these ambiguities are generally resolved by adding precedence rules or other context-sensitive parsing rules, so the overall phrase structure is unambiguous. Context-free languages have many applications in programming languages, in particular, most arithmetic expressions are generated by context-free grammars. A string of terminals and/or nonterminals α is called a α -string.

Generalized context-free grammar Generalized context-free grammar (GCFG) is a grammar formalism that expands on context-free grammars by adding potentially non-context-free composition functions to rewrite rules. Head grammar (and its weak equivalents) is an instance of such a GCFG which is known to be especially adept at handling a wide variety of non-CF properties of natural language.
