Trypanosoma International Journal for Parasitology, 1 May 2001, Volume 31, Issues 5–6, Pages 643–647, doi:10. Trypanosoma equiperdum is spread between horses and other equine species by sexual contact. The majority of species are transmitted by blood-feeding invertebrates, but there are different mechanisms among the varying species. The name is derived from the Ancient Greek trypano- (borer) and soma (body) because of their corkscrew-like motion. 1016/S0020-7519(01)00138-2 Dihydrofolate reductases within the genus Trypanosoma is a genus of kinetoplastids (class Trypanosomatidae), a monophyletic group of unicellular parasitic flagellate protozoa. Most trypanosomes are heteroxenous (requiring more than one obligatory host to complete life cycle) and most are transmitted via a vector. Trypanosoma is part of the phylum Euglenozoa. They are generally found in the intestine of their invertebrate host, but normally occupy the bloodstream or an intracellular environment in e3110b1938
